Some of the causes of vibration include asymmetry in the mechanical device, asymmetric loads being applied, and asymmetric mass distribution. Even very small amounts of torsional vibration can be detrimental to performance, even if no noise is perceived by the operator. Certain conditions are also present in some systems that affect vibration dynamics. Such conditions may include damping and critical damping. Damping affects the response of the mechanical system to applied vibration in both the translational and rotational directions. If the damping is small in magnitude, the mechanical system vibrates at a constant frequency. The amplitude of vibration is affected by damping. The frequency at which the system vibrates is defined as the natural frequency of the system. The term damping is used to describe the tendency of a system to resist changes in the natural frequency. This definition is derived from the temperature-time relationship of a thermostat where the time needed to reduce the temperature of a system back to a specified value is proportional to the thermal capacity of the system and inversely proportional to the natural frequency. Thus, when vibration is applied to the system, or during relaxation of the system, the system will move to a new state of equilibrium at the natural frequency. The new state of equilibrium of the

system is the final state of the system. If damping in the system is different at the angular and translational frequencies of the system, the system will achieve the new equilibrium at a frequency that is different from the original equilibrium frequency. Vibration can occur between the original and new equilibrium frequencies. Critical damping occurs when a system has a natural frequency and damping such that the vibration amplitude is amplified 6d1f23a050
